(54) Title: IMPROVED MATERIAL FOR USE WITH FERROELECTRICS

(57) Abstract: A liner layer comprising TiO<sub>2</sub> enriched SRO is disclosed. The TiO<sub>2</sub> enriched SRO liner improves the reliability of ferroelectric materials such as PZT without adversely impacting or degrading the ferroelectric properties of the PZT. The **SRTO**, in one embodiment is sputtered using an SRO target doped with 1-10% TiO<sub>2</sub>.

WO 03/021656 A2

**IMPROVED MATERIAL FOR USE WITH FERROELECTRICS****FIELD OF THE INVENTION**

5       The present invention relates to ferroelectric integrated circuits and, more particularly, to materials that reduces fatigue in the ferroelectric material.

**BACKGROUND OF THE INVENTION**

10       Ferroelectric metal oxide ceramic materials such as lead zirconate titanate (PZT) have been investigated for use in ferroelectric semiconductor memory devices. A memory cell of the ferroelectric memory device includes a capacitor which serves as the storage element. Fig. 1  
15       shows a conventional ferroelectric capacitor 101. As shown, the capacitor comprises a ferroelectric metal oxide ceramic layer 150 sandwiched between first and second electrodes 110 and 120. The electrodes typically are formed from a noble metal such as platinum.

20       The ferroelectric capacitor uses the hysteresis polarization characteristic of the ferroelectric material for storing information. The logic value stored in the memory cell depends on the polarization of the ferroelectric capacitor. To change the polarization  
25       of the capacitor, a voltage which is greater than the

to a performance degradation of the ferroelectric capacitor.

To counterbalance the loss of  $\text{RuO}_2$  during crystallization, an SRO target with excess  $\text{RuO}_2$  is used.

5 However, the excess  $\text{RuO}_2$  diffuses and reacts with the ferroelectric layer during high temperature crystallization of the ferroelectric material which degrades its ferroelectric properties.

From the foregoing discussion, it is desirable to  
10 provide an improved material which reduces fatigue without adversely impacting its ferroelectric properties.

#### SUMMARY OF THE INVENTION

15 The invention relates to the use of materials which reduces fatigue in ferroelectric materials without adversely affecting its ferroelectric properties. In one embodiment of the invention, the material comprises SRO which is enriched with  $\text{TiO}_2$ . The SRO comprises about  
20 1-10 atomic weight percent (unless otherwise specified, all percentages are in atomic weight percent) of  $\text{TiO}_2$ . In one embodiment, the  $\text{TiO}_2$  enriched SRO is formed on a substrate which is processed to include a first or bottom capacitor electrode. A ferroelectric material

such as PZT is formed on the TiO<sub>2</sub> enriched SRO. Subsequently, a second TiO<sub>2</sub> enriched SRO layer is formed on the ferroelectric layer followed by formation of the upper electrode. In one embodiment, the SRO enriched  
5 layer is formed by sputtering using an SRO target doped with 1-10 percent % TiO<sub>2</sub>.

#### BRIEF DESCRIPTION OF DRAWINGS

Fig. 1 shows a conventional ferroelectric  
10 capacitor;

Fig. 2 shows a ferroelectric capacitor in accordance with one embodiment of the invention;

Fig. 3 shows an illustrative system for depositing the TiO<sub>2</sub> enriched SRO layer in accordance with one  
15 embodiment of the invention; and

Fig. 4 shows an SRT0 layer after a crystallization anneal.

#### DETAILED DESCRIPTION OF THE INVENTION

20 Fig. 2 shows a ferroelectric capacitor 201 in accordance with one embodiment of the invention. Such a capacitor, for example, is used to form a ferroelectric memory cell of a ferroelectric memory IC. As shown, the capacitor comprises first and second electrodes 210 and

220. The electrodes are formed from, for example, platinum or a noble metal such as Ir, Pd, IrO<sub>2</sub> or other conducting oxides. A ferroelectric layer 150 is located between the electrodes. In one embodiment, the ferroelectric material comprises PZT or lead-lanthanum-zirconium-titanate (PLZT). Other types of ferroelectric material, such as Strontium-bismuth-tantalate (SBT) may also be used.

Liner layers 230a-b are provided between the electrodes and the ferroelectric layer to reduce fatigue in the ferroelectric layer. In accordance with the invention, the liner layer comprises TiO<sub>2</sub> enriched SRO (e.g., TiO<sub>2</sub> doped SRO). The TiO<sub>2</sub> increases the stability of the SRO layer which in turn, reduces the formation of flowerlike features. In one embodiment, the SRO is doped with 1-10 percent of TiO<sub>2</sub>. Greater than 10% of TiO<sub>2</sub> in the SRO film can increase the sheet resistance of the TiO<sub>2</sub> enriched SRO layer beyond desirable limits, thus adversely impacting the performance of the capacitor.

In one embodiment, the thickness of the TiO<sub>2</sub> enhanced SRO layer is about 5-50nm, the ferroelectric layer is about 100-200nm, and the electrode is about 10-100nm. The preferred thickness of the TiO<sub>2</sub> doped SRO is in the range

of 5-50 nm, typical PZT thicknesses are 100-200 nm, Pt  
10-100 nm.

The  $\text{TiO}_2$  enriched SRO layer is sputtered, in one  
embodiment, on the substrate. Fig. 3 shows a sputtering  
5 system 301 used to deposit the  $\text{TiO}_2$  enriched SRO layer.  
The system includes a substrate support 305 on which a  
substrate is mounted. The substrate has been processed  
to include, for example, a conductive layer such as  
platinum to serve as the bottom electrode of the  
10 capacitor. Depending on the process, the conductive  
layer can be patterned or not. The system also includes  
a sputtering target 310 comprising a SRO ceramic  
compound enriched with 1-10 percent of  $\text{TiO}_2$ .

During the sputtering process, atoms from the  
15 target react to form an amorphous layer 330 consisting  
of  $\text{SrO}$ ,  $\text{TiO}_2$  and  $\text{RuO}_2$  on the substrate. The parameters  
of the sputtering process, for example, are as follows:

Pressure: 0.5 -1 Pa

Temperature: room temperature to  $650^\circ\text{C}$

20 Power: 500-1000 W

Reactive gas: Ar gas with 5 - 50 % volume weight %

After deposition, the amorphous film is crystallized by  
an annealing process at, for example, a temperature of  
450 -  $700^\circ\text{C}$  for about 30 seconds to 5 minutes. During

the anneal, excess SrO is transformed into SrTiO<sub>3</sub> (STO). STO is a stable material having a perovskite structure similar to that of PZT and other types of ferroelectric materials. The TiO<sub>2</sub> enriched SRO layer may also contain  
5 unreacted TiO<sub>2</sub> grains 434, as shown in Fig. 4. The STO and unreacted TiO<sub>2</sub> grains serve as nucleation sites for the subsequently formed ferroelectric layer, triggering a very uniform grain structure in the ferroelectric layer and improved ferroelectric properties.

10 After the crystallization of the TiO<sub>2</sub> enriched SRO layer, the process continues to form the ferroelectric capacitor and completion of the IC. This, for example, includes forming the ferroelectric layer, the second TiO<sub>2</sub> enriched SRO layer, upper electrode, interconnects and  
15 interlevel dielectrics, passivation layer and packaging.

While the invention has been particularly shown and described with reference to various embodiments, it will be recognized by those skilled in the art that modifications and changes may be made to the present  
20 invention without departing from the spirit and scope thereof. The scope of the invention should therefore be determined not with reference to the above description but with reference to the appended claims along with their full scope of equivalents.

What is claimed is:

1. A method for forming a ferroelectric capacitor comprising:

5 providing a substrate having a first conductive layer formed thereon, the first conductive layer serves as a electrode of the capacitor;

depositing a first amorphous liner layer on the electrode;

10 depositing a ferroelectric layer on the first liner layer;

depositing a second amorphous liner layer on the ferroelectric layer; and

depositing a second conductive layer on the liner  
15 layer, the second conductive layer serves as a second electrode, wherein the liner layer comprises SRO enriched about 1-10%  $\text{TiO}_2$  weight percent, wherein the liner layers improve the properties of the ferroelectric layer.

20

2. The method of claim 1 wherein the ferroelectric layer comprises PZT.

3. The method of claim 2 wherein the first electrode  
25 comprises a noble metal.

4. The method of claim 3 wherein the first electrode comprises platinum.

5 5. The method of claim 1 wherein the electrodes comprise a noble metal.

6. The method of claim 5 wherein the electrodes comprise platinum.

10

7. The method of claim 1,2,3,4,5 or 6 further comprises an annealing process to crystallize the  $\text{TiO}_2$  enriched SRO layer.

15 8. The method of claim 7 wherein the annealing process comprise heating the  $\text{TiO}_2$  enriched SRO layer at a temperature of about  $650^\circ\text{C}$  for about 30 sec.

9. The method of claim 8 further comprising the steps  
20 for completing a ferroelectric memory IC.

10. The method of claim 7 further comprising the steps for completing a ferroelectric memory IC.

11. A method for forming a ferroelectric capacitor comprising:

depositing a first amorphous layer on a substrate;

depositing a ferroelectric layer on the first liner

5 layer;

depositing a second amorphous liner layer on the ferroelectric layer; and

depositing a second conductive layer on the liner layer, the second conductive layer serves as a second

10 electrode, wherein the liner layer comprises SRO

enriched with about 1-10%  $\text{TiO}_2$ , wherein the liner layers improves the properties of the ferroelectric layer.
